Stockwise Smart Inventory

Stockwise helps a single-store business manage products, stock, suppliers and purchasing in one web application. This guide shows the main screens using a cleaning-products demonstration inventory.

The dashboard brings stock value, units on hand, low-stock alerts and open purchase orders together. A sales chart shows recorded demand and a baseline forecast for the next 14 days.

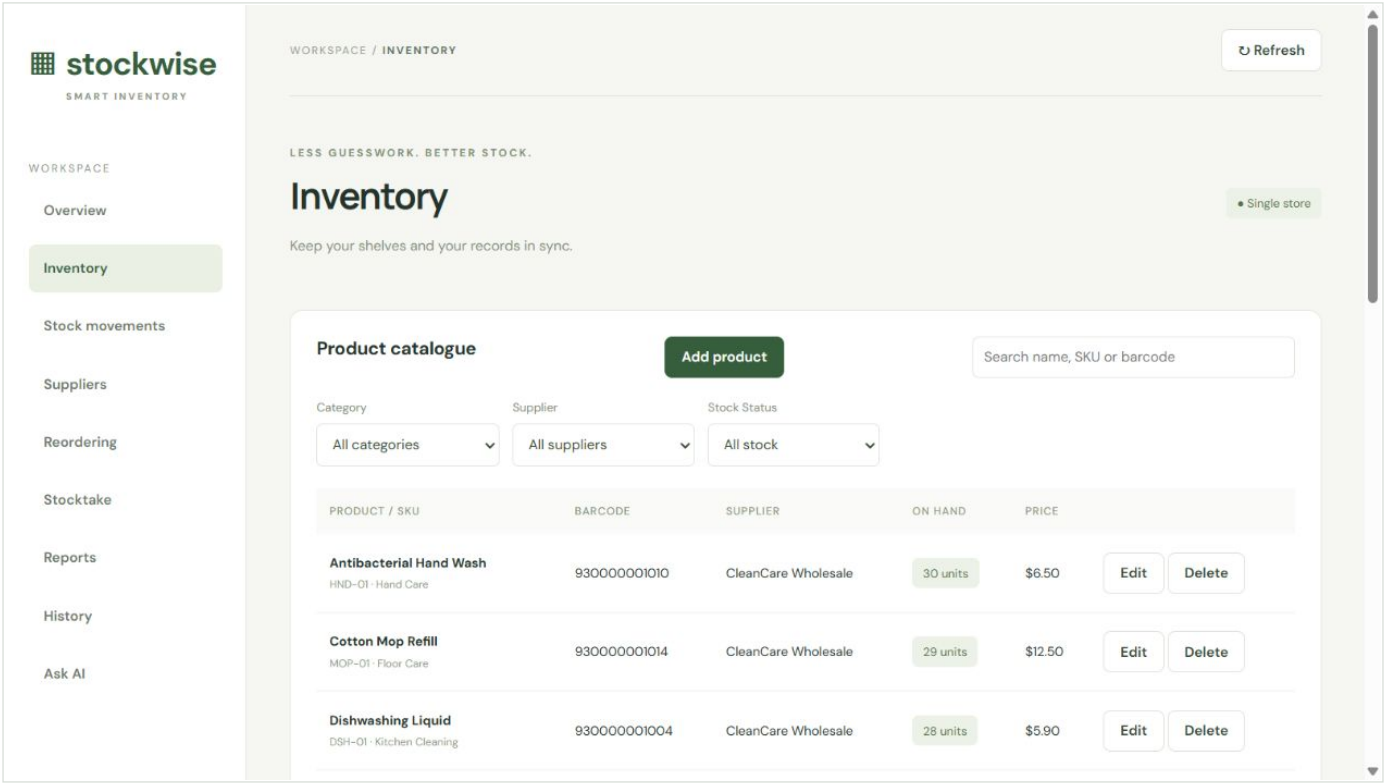

Overview with inventory metrics, demand chart and low-stock alerts.

Find and manage your products

Keep product names, SKUs, barcodes, categories, suppliers, selling prices and unit costs in a central catalogue. Search by name, SKU or barcode, then filter by category, supplier or stock status.

Add, edit and delete product records from the catalogue. CSV tools support inventory and transaction exports, plus product import. Stock quantities change through receipts, sales, adjustments or stocktakes.

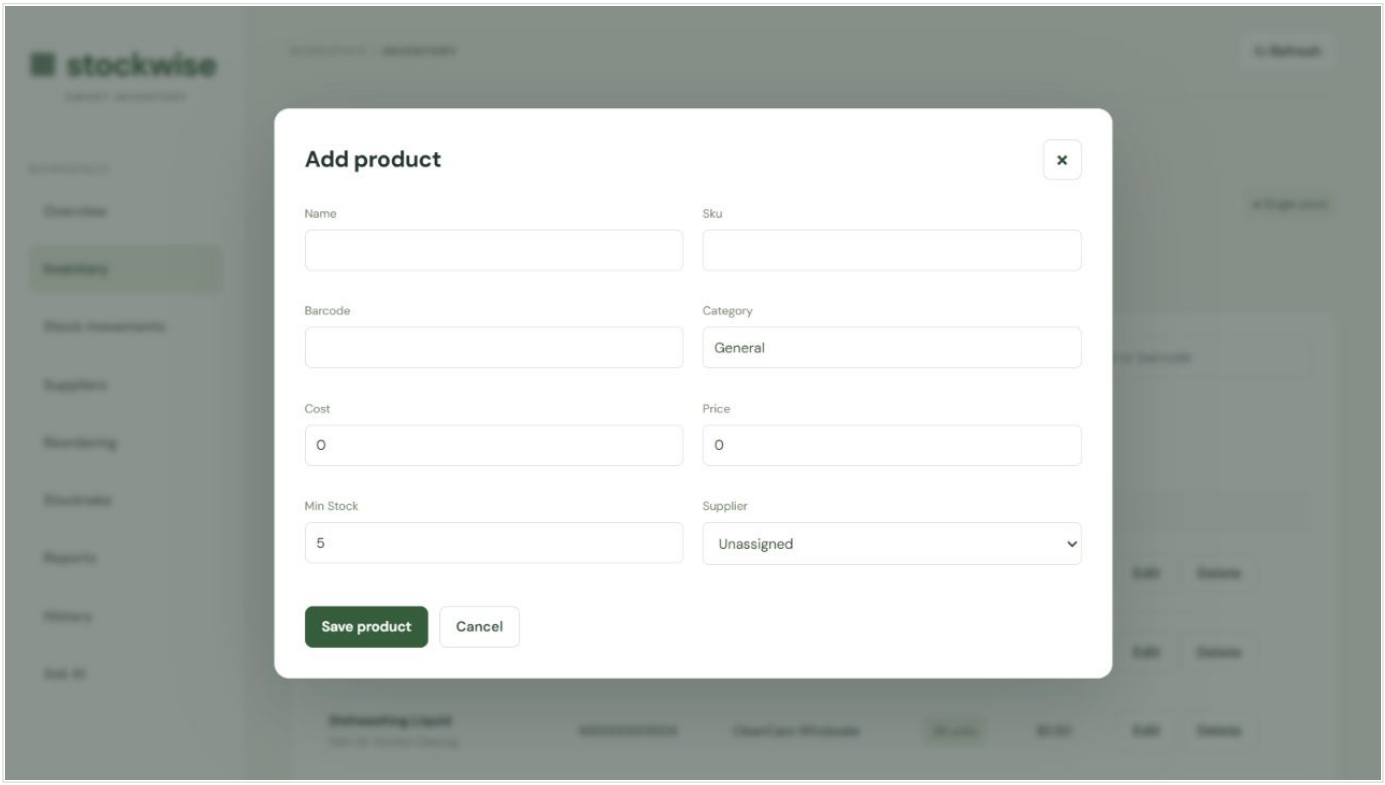

Inventory catalogue with cleaning products, search, filters and edit controls.

Make changes in clear popup forms

Add and edit records in popup dialogs while keeping the current screen in view. Product forms include unit cost, selling price, minimum stock and supplier assignment.

Record sales, receipts and signed stock adjustments from Stock movements. Barcode lookup can select a product for a movement. Stocktake compares a physical count with the recorded balance. History records changes for review.

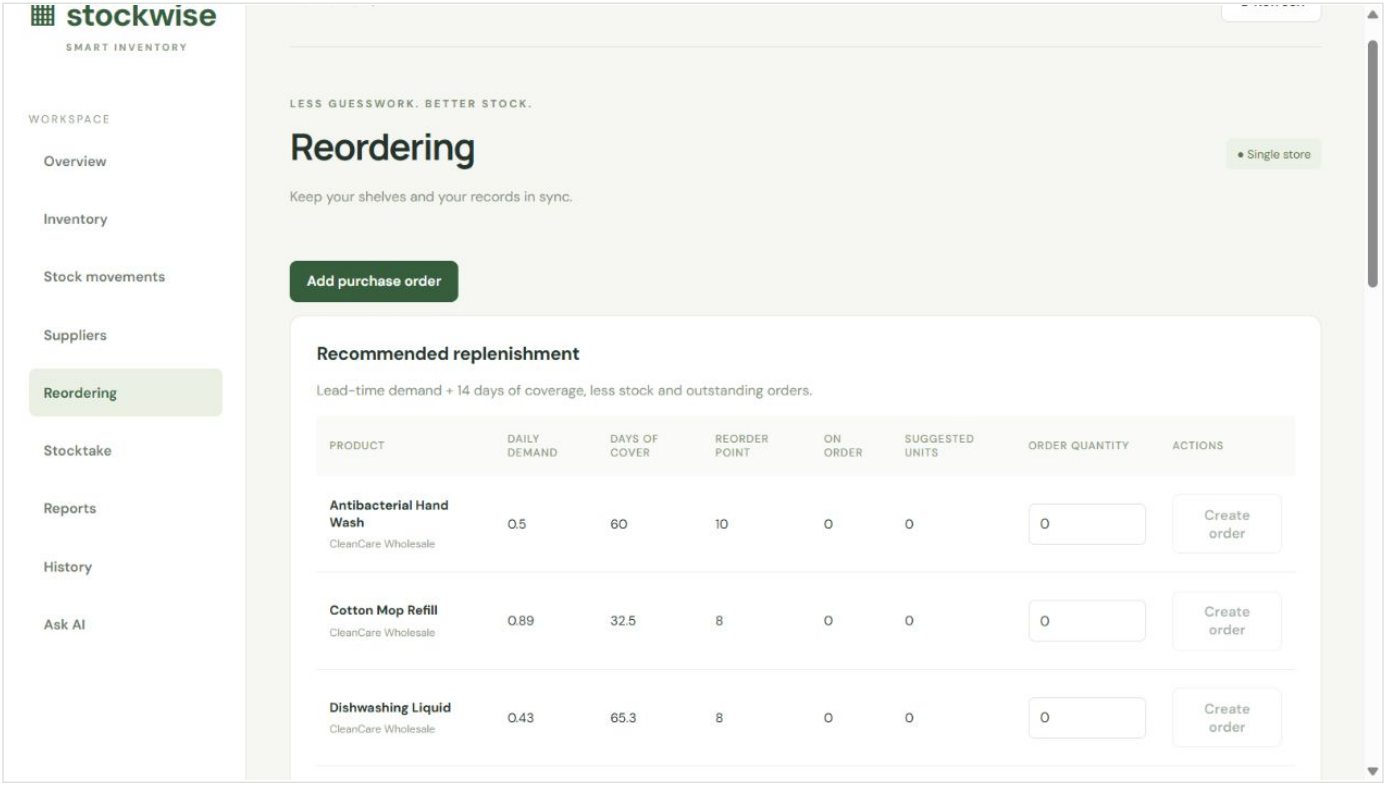

The Add product dialog presents the information needed to create a catalogue entry.

Plan and receive replenishment

Review demand, days of cover, reorder points, outstanding orders and suggested units together. Type the quantity you want in Order quantity, then choose Create order to use that amount.

Purchase orders track ordered, received and remaining units, plus an expected delivery date. Receive a full delivery or part of an order as stock arrives. Supplier lead times support replenishment estimates.

Suggestions use recent sales and supplier lead times. They are baseline estimates and do not model seasonality or lost demand during stockouts.

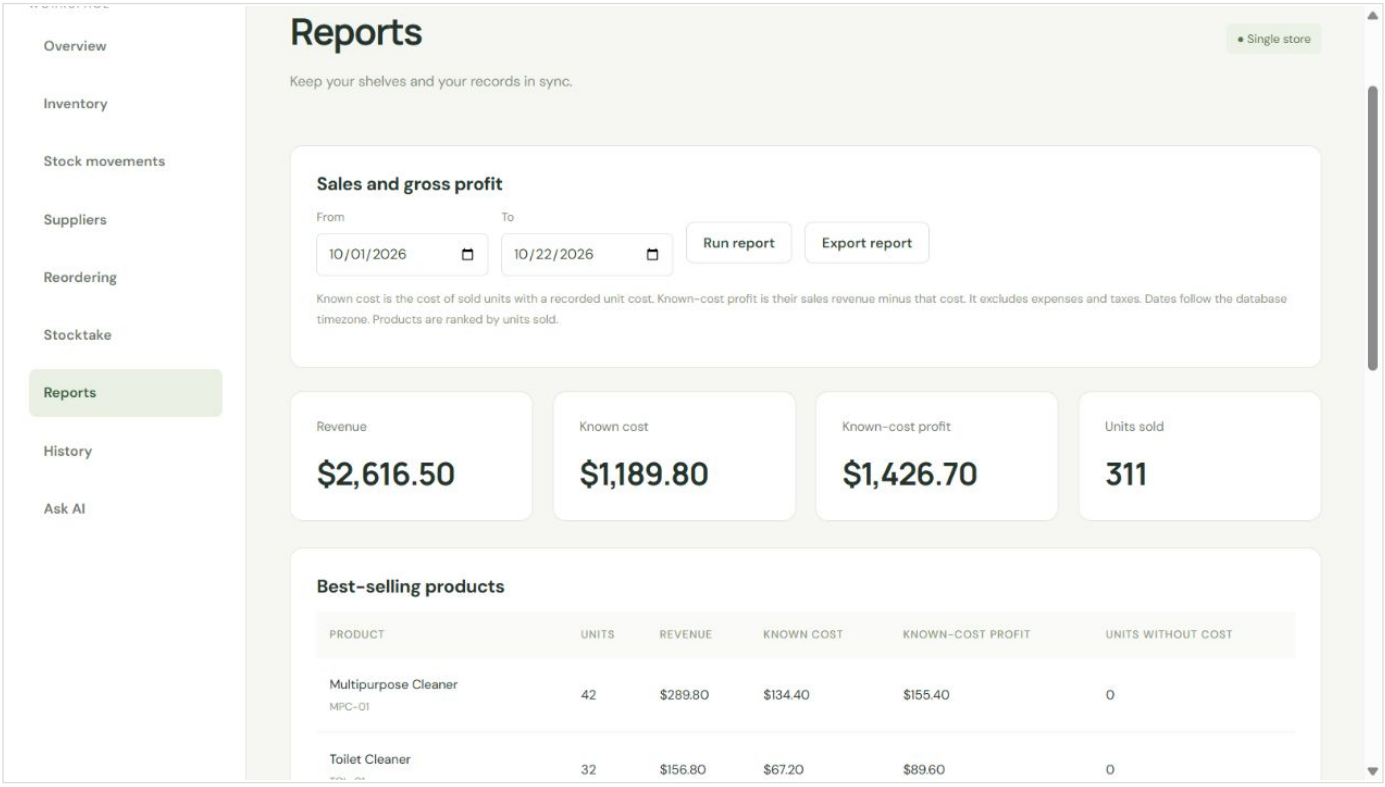

Reordering shows editable order quantities beside the calculated suggestions.

See sales and known cost profit

Choose a date range to view revenue, units sold, known cost and known-cost profit. The product table ranks best sellers and shows units without a recorded cost. Export the report for further review.

Known cost is the recorded unit cost of sold units. **Known-cost profit** is the revenue from those costed units minus their recorded cost. It excludes operating expenses and taxes; sales missing a cost are excluded from the profit calculation.

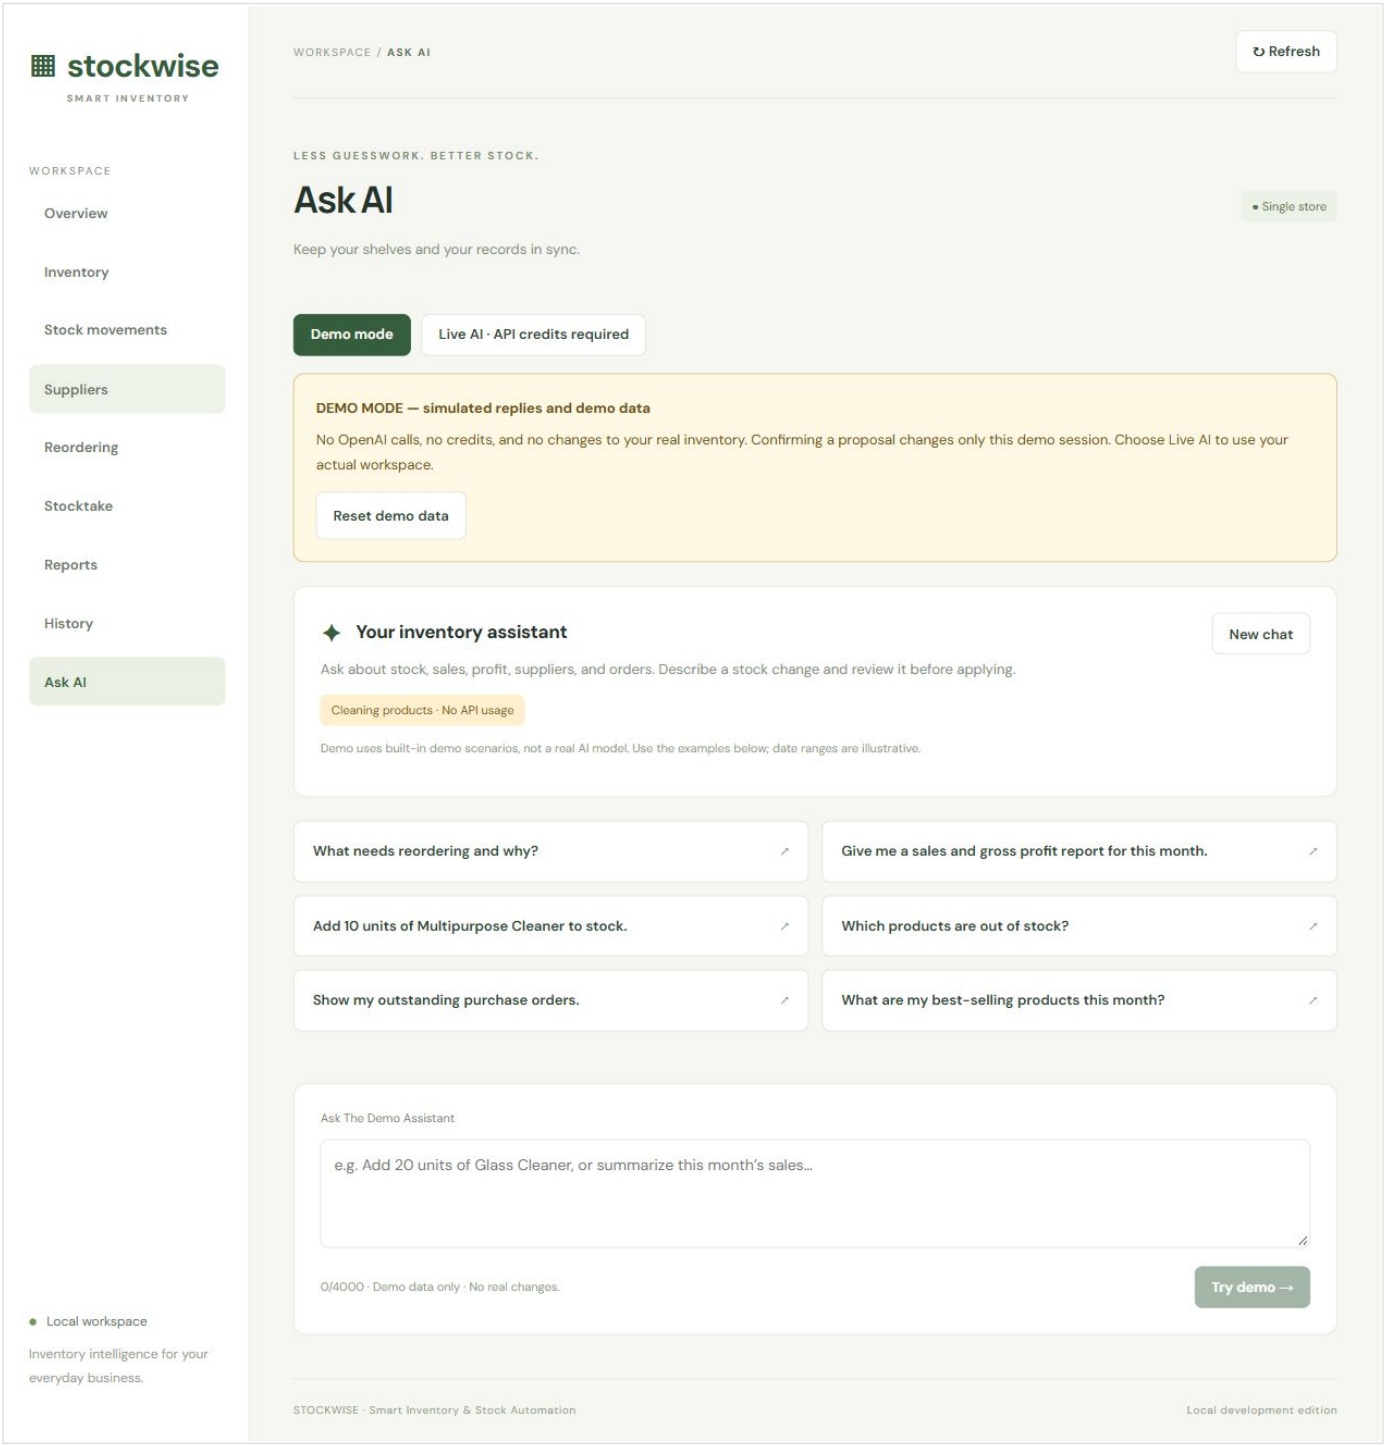

Sales report with known cost and known-cost profit summary cards.

Ask questions and review stock actions

Use prompts to explore inventory, sales, profit and replenishment, or prepare a stock change or purchase order. Review the proposed action before confirming it.

Demo mode uses built-in cleaning-product scenarios with no API credits or changes to the main inventory. Live AI uses the backend OpenAI connection and requires available API credits. The API key stays on the server.

Ask AI clearly labels the demo experience and offers prompts to begin.

How the application is built

The frontend is the part users see in the browser. The backend receives requests, checks the data and updates the database. This separation keeps business rules and the AI connection on the server.

Layer	Technology	Purpose
Frontend	React 19 and TypeScript	Builds the browser screens, forms and interactions.
Build and styling	Vite 7 and CSS	Develops and bundles the interface; CSS defines its layout and appearance.
Charts	Recharts 3	Displays recorded sales and the demand forecast.
Backend	Node.js, Express 5 and TypeScript	Provides the JSON API and applies inventory and purchasing rules.
Database	PostgreSQL with the pg driver	Stores products, suppliers, movements, orders and change history.
Validation and jobs	Zod and node-cron	Validates incoming data and runs scheduled inventory jobs.
AI integration	OpenAI Responses API	Supports live AI requests through server-side tools and reviewed action proposals.

How a stock change works

A user submits a form in React. The Express API validates the request and records the movement in PostgreSQL. The stock balance and history are updated, then the browser refreshes the displayed inventory.

A short showcase walkthrough

1. Open Overview and point out the low-stock alerts and demand chart.

2. Search Inventory for Glass Cleaner and open Edit to show the popup form.

3. Open Reordering and explain how Order quantity overrides the suggestion.

4. Open Reports and explain revenue, known cost and known-cost profit.

5. In Ask AI Demo mode, try Add 10 units of Multipurpose Cleaner to stock and review the simulated proposal.

The captured application is the local single-store edition. The screenshots show the workspace as captured; balances change as transactions are edited or recorded.
